

COMVOLY

V2 product design review

A mobile-friendly summary of the proposed owner, member, platform, history, media, permission, pilot, and implementation experience.

FOUNDER REVIEW PACK

28 July 2026

AI that interprets community knowledge

Comvolvy is an AI-powered intelligence layer for online communities. It does more than find old messages: it interprets the accumulated conversation, experience, recommendations, decisions, patterns, and resources inside an authorised community.

Turn the wealth of knowledge inside a community into clear, useful intelligence - with every insight grounded in the conversations and evidence behind it.

What makes Comvolvy different

The AI interprets knowledge across a community's authorised history - connecting related conversations, surfacing patterns, distinguishing consensus from disagreement, and transforming fragmented discussion into useful intelligence. Every result remains grounded in original evidence.

Core product decisions

- AI interpretation is the core product; search is one supporting capability.
- Answers, catch-ups, patterns, decisions, and recommendations remain cited.
- One Comvolvy account spans every owned and joined community.
- Each community remains a separate, permission-controlled workspace.
- Historical knowledge and media are central to first-day value.
- Owners connect once; ordinary members never configure integrations.

Accounts, communities, and roles

One human account can link Telegram, Discord, recovery identity, and future approved providers. Linked identities prove platform identity; they do not combine permissions or content.

Role	Primary responsibilities
Owner	Billing, sources, retention, export, deletion, all settings
Administrator	Connections, imports, members, scope, reports
Moderator	Curation, concerns, member support
Member	Ask, Search, Catch Up, Explore, Save

Separation rule

Every content item, import, answer, citation, media object, job, membership, and usage event belongs to one immutable workspace. Authorisation occurs before retrieval, not after results are produced.

Personal multi-community features

A member may later select several authorised workspaces for a personal catch-up. Retrieval remains separate per workspace, every citation names its community, and owners gain no visibility into unrelated selections or results.

Owner journey

Step	Owner experience
1	Create a private workspace
2	Choose Telegram, Discord, or approved Skool route
3	Connect and verify owner authority
4	Choose channels, history, dates, and media
5	Bring previous history
6	Review counts, omissions, processing, and cost
7	Set access, retention, and community notice
8	Process history while ongoing updates continue
9	Test Search and cited Ask results
10	Activate and invite members

The workspace stays administrator-only until review. Setup progress survives browser closure and failures identify a safe next action.

Owner screen concepts

Create your community

Private during setup

Community name

Purpose and owner role

No developer credentials

[Choose platform]

Connect Telegram safely

Two complementary parts

1. Add Comvolvy for new activity and membership
2. Bring a Telegram Desktop export for previous history

Verified group, authority, and bot status

[Choose content]

Review before processing

Nothing processed until confirmation

Date range, message/member/media counts

Unsupported or protected items

Storage and optional processing estimate

[Confirm import]

Member journey

Members do not connect a shared chat again. They use one Comvolvy account, link the relevant platform identity, and prove membership or await administrator approval.

Step	Member experience
1	Follow a community-specific invitation or pinned link
2	Sign in with an existing Comvolvy account or create one
3	Link the required platform identity if not already linked
4	Verify current membership or request administrator approval
5	See archive coverage, freshness, privacy, and first actions
6	Ask, Catch Up, Explore, Search, and Save
7	Switch communities without combining them

Access lifecycle

Confirmed departure from a source community suspends that workspace membership. The person's Comvolvy account and access to other communities remain intact.

Member screen concepts

Account home

Everything you own and belong to

Owned and administered communities

Joined communities

Catch-ups and saved knowledge

Role, provider, and freshness shown clearly

[Open workspace]

Workspace overview

Lead with value, not vanity counts

Catch up since last visit

Recent decisions, questions, and recommendations

Suggested questions and followed topics

Archive coverage and freshness

[Catch me up]

Ask with evidence

Based only on permitted archive content

Concise answer with citation markers

Supporting and conflicting messages

Missing, old, or uncertain evidence stated

Save, refine, report, open context

[Ask a follow-up]

The useful product, not only search

Surface	Member value
Ask	Grounded questions with original evidence
Catch Up	Decisions, questions, recommendations, links, notable discussion
Explore	Topics, FAQs, decisions, recommendations, files, curated knowledge
Search	Exact words or meaning-based discussions with filters/context
Saved	Private answers, source items, and personal collections

Example jobs

- What did we decide about the next event?
- Which installer did members repeatedly recommend?
- What have I missed since Friday?
- Show the document shared about insurance.
- Which questions keep being asked by new members?

Telegram design

The existing prototype works by authorising a real Telegram user session. That proves historical retrieval but is too powerful and technical for customer onboarding.

Production decision

Use an owner-provided Telegram Desktop JSON/media export for history, plus a branded Comvolvy bot for ongoing messages, membership checks, setup, notices, and optional commands.

Bot responsibilities

- Verify the connected group and owner/admin status.
- Collect new authorised messages and media after connection.
- Support membership verification and group notices.
- Provide /ask, /catchup, /help, and /privacy where useful.
- Report connection health and allow pause/disconnect.

History responsibilities

- Preview before processing and detect a mismatched export.
- Import text, replies, authors, dates, media relationships, and supported files.
- Deduplicate overlap with ongoing bot events.
- Remain resumable and produce an item-level report.

Discord confirmed; Skool conditional

Discord

Official APIs support owner-authorised channel discovery, paginated historical messages, active and archived threads, attachments, ongoing events, OAuth identity, and membership checks. Required channel permissions and privileged Message Content/Guild Members intents must be handled before scale.

Skool

A full production connector is not yet confirmed. Official published Zapier/API-key uses do not establish complete historical access to posts, comments, chat, classroom material, media, and member lifecycle.

Acceptable Skool route	Status
Documented official API	Validate scope and terms
Comprehensive owner export	Possible import beta
Written partnership/private API	Possible full connector
Scraping/browser credentials	Not acceptable

The architecture remains platform-neutral, but Comvolvy does not advertise a capability until its approved route is proven.

Historical import and media

Import lifecycle

Upload -> Validate -> Preview -> Confirm -> Parse -> Store -> Extract -> Index -> Owner review -> Activate

Preview must show

- Community/source match, date range, message and participant counts.
- Media counts and bytes by type, unsupported/protected items, and overlap.
- Selected retention, storage, external processing, and estimated allowance.

Pilot media boundary

- Securely inventory and display permitted images/files.
- Extract text from common documents and opt-in screenshots.
- Cite extracted content through its original message and attachment.
- Defer broad video transcription and general image understanding.

Separate consent

Storing media and sending media to an external AI processor are different settings. Raw upload archives are deleted after a short verification window unless explicitly retained.

Product and security acceptance

The specification contains 52 stable pilot requirements across accounts, workspaces, onboarding, ingestion, value, controls, and usage.

Non-negotiable acceptance

- Every request authorises account, active membership, role, workspace, and source scope.
- Tenant isolation is tested across API, retrieval, background jobs, media URLs, caches, and exports.
- Imports resume safely and are idempotent.
- Owners can pause, export, and delete without developer intervention.
- Answers cite evidence and label missing, conflicting, or stale support.
- Platform tokens and bot credentials are encrypted and never returned to browsers.
- Community content is not used for model training.

Pilot performance targets

Experience	Target
Account/workspace useful content	2 sec p75
Exact search	2 sec p95
Typical cited answer	15 sec
Import progress freshness	10 sec

Invitation-only private pilot

Initial cohort

- 3-5 owner-led private communities and 10-50 active members.
- At least two established Telegram archives with media.
- One Discord test community during the pilot.
- Skool discovery/import experiment only with approved access.
- Avoid highly regulated or safety-critical communities initially.

What success means

- A non-technical owner connects/imports with minimal assistance.
- At least 90% of selected historical text imports successfully.
- Media inventory matches the source export within agreed tolerance.
- Members return for cited answers or catch-up without owner prompting.
- Owner reports fewer repeated questions or faster retrieval.
- No cross-workspace access failures.
- Infrastructure and AI cost per workspace is known.

Implementation roadmap

Stage	Outcome
0	Keep founder prototype private; backups, limits, rate protection
1	Accounts, workspaces, roles, tenant isolation, audit, jobs, storage
2	Telegram bot plus history/media import and owner review
3	Member invitation, multi-community home, Ask/Search/Catch Up/Explore
4	External Telegram pilot, cost/quality/support measurement
5	Discord beta with history, threads, events, membership
6	Pricing test and broader-beta readiness

Implementation starts with security boundaries

Do not begin with another connector or visual redesign. First build accounts, linked identities, workspaces, roles, and negative tenant-isolation tests.

Gates and risks

Risk	Gate or mitigation
Cross-workspace leakage	Server scope plus negative tests everywhere
Telegram terms/AI conflict	Policy/legal review before external pilot
Skool access unavailable	Conditional roadmap; no scraping/promises
Discord intents unavailable	Apply early; explicit beta gate
Export setup too hard	Observed usability tests; resumable flow
Owner/member trust	Authority, notice, scope, reporting, deletion
Media cost	Preview estimates, opt-in processing, limits
Misleading AI answers	Evidence, uncertainty, curation, reporting

External decisions involving platform permission, legal basis, meaningful spend, live-data migration, or public launch remain explicit approval gates.

Founder review checklist

Approve or revise these working decisions:

- Established private paid/professional communities as the first segment.
- Telegram Desktop export plus ongoing bot as the launch history route.
- Discord beta as the second confirmed connector.
- Skool remains conditional on approved access.
- Secure media display and document/screenshot text as pilot scope.
- Owner-sponsored workspace with included member access.
- Invitation-only pilot with hands-on founder onboarding.
- No model training on community content.
- Personal cross-community AI deferred until isolation is proven.

Next action after approval

Run low-fidelity usability sessions with 3-5 prospective owners/members, revise the journey, then begin the secure multi-tenant foundation.

Full detailed specifications are stored in the private Comvolvy GitHub repository under docs/product.
